O.K.Andersen

Electronic structure of solids and surfaces

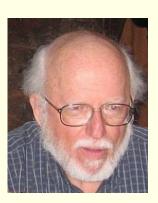

Phys.Rev.Lett. 98, 106802 (2007)

K.Schwarz, P.Blaha, S.B.Trickey, Molecular physics, **108**, 3147 (2010)

Wien2k is used worldwide by about 2500 groups

The WIEN2k code: comments

- Walter Kohn: density functional theory (DFT), 1965
- J.C.Slater: augmented plane wave (APW) method, 1937
- O.K.Andersen: Linearized APW (LAPW), 1975
- Wien2k code: developed during the last 35 years
 - In the year 2000 (2k) the WIEN code (from Vienna) was called wien2k
 - One of the most accurate DFT codes for solids
 - All electron, relativistic, full- potential method
 - Widely used in academia and industry

Applications:

- <u>solids:</u> insulators , covalently bonded systems, metals
- Surfaces: catalysis
- Electronic, magnetic, elastic , optical ,...properties
- Many application in literature
- See <u>www.wien2k.at</u>

Aspects at this workshop

- Atomic structure
 - Periodic boundary condition (approximation)
- Quantum mechanical treatment
 - DFT (functionals) and beyond (GW, DMFT, RPA, BSE, ...)
- How to solve the QM (basis set)
 - LAPW method and local orbitals as implemented in WIEN2k
- Applications
 - Verwey transition, EFG, NMR, surfaces, spectra
- Software development
 - Accuracy, efficiency, system size, user-friendliness, commercial
- Insight and understanding
 - Analysis to find trends, computer experiments (artificial cases)
- Combination of expertise
 - Chemistry, physics, mathematics, computer science, application

Four big challenges for theorists:

- large scale applications to simulate "real" materials
 - at the atomic scale
- A proper quantum mechanical treatment (accurate)
 - develop more accurate DFT functionals
 - beyond DFT (GW, DMFT, BSE, RPA...)
- Efficiency (make calculations faster):
 - improve numerics, parallelization, algorithms (iterative diagonalization)
- calculate "new" properties
 - for direct comparison with experiment

The atomic structure

A crystal is represented by a unit cell

- We assume periodic boundary condition (approximation)
- The unit cell is repeated to infinity (makes calculations feasible)
- A real crystal is finite (with surfaces, impurities, defects ...)
- Nano materials differ from bulk
- Symmetry helps (space group, Bloch theorem, ...)

In theory

- The atomic structure is an input and thus well defined.
- Artificial structures can be studied too

In experiment

- The atomic structure is not perfectly known
- Single crystals, micro crystals, powder samples, nano
- e.g. by X-ray: averaged with uncertainties (defects, disorder)

A few solid state concepts

Crystal structure

- Unit cell (defined by 3 lattice vectors) leading to 7 crystal systems
- Bravais lattice (14)
- Atomic basis (Wyckoff position)
- Symmetries (rotations, inversion, mirror planes, glide plane, screw axis)
- Space group (230)
- Wigner-Seitz cell
- Reciprocal lattice (Brillouin zone)

Electronic structure

- Periodic boundary conditions
- Bloch theorem (k-vector), Bloch function
- Schrödinger equation (HF, DFT)

Assuming an ideal infinite crystal we define a unit cell by

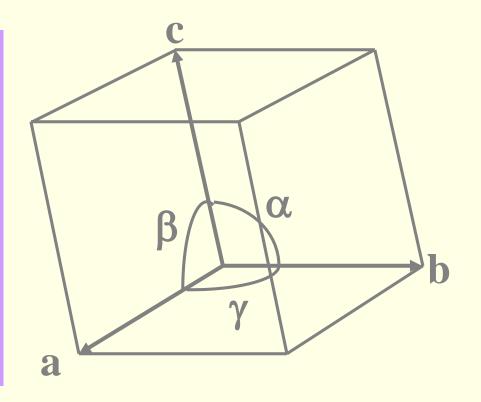

Unit cell: a volume in space that fills space entirely when translated by all lattice vectors.

The obvious choice:

a parallelepiped defined by **a**, **b**, **c**, three basis vectors with

the best **a**, **b**, **c** are as orthogonal as possible

the cell is as symmetric as possible (14 types)

A unit cell containing one lattice point is called primitive cell.

Crystal system: e.g. cubic

Axis system

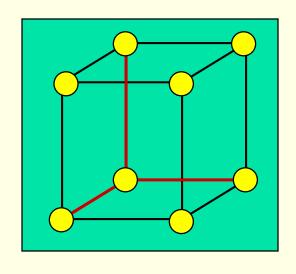

$$a = b = c$$

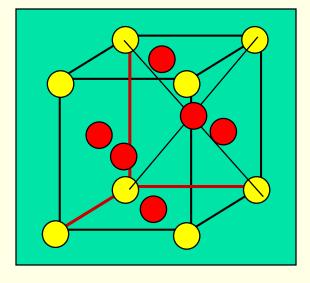

$$\alpha = \beta = \gamma = 90^{\circ}$$

primitive

body centered

face centered

P (cP)

I (bcc)

F (fcc)

3D lattice types:

7 Crystal systems and 14 Bravais lattices

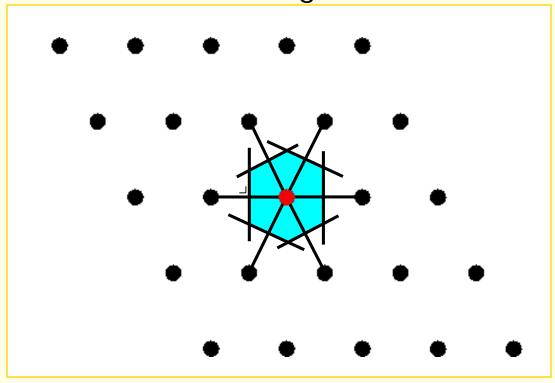

Triclinic	1	"no" symmetry	
Monoclinic (P, C)	2	Two right angles	
Orthorhombic (P, C, I, F)	4	Three right angles	
Tetragonal (P, I)	2	Three right angles + 4 fold rotation	
Cubic (P, I, F)	3	Three right angles + 4 fold + 3 fold	
Trigonal (Rhombohedral)	1	Three equal angles (≠ 90°)+ 3 fold	
Hexagonal	1	Two right and one 120° angle + 6 fold	

Wigner-Seitz Cell

Form connection to all neighbors and span a plane normal to the connecting line at half distance

The quantum mechanical treatment

- The electronic structure requires a QM treatment
- The main scheme is density functional theory (DFT)
 - It is a mean field approach and requires approximations
 - According to Hohenberg Kohn it is sufficient to know the electron density of a system to determine its total energy. The many electron wave function (which depends on many variables) is not needed. In principle this is an enormous simplification, but in practice approximations must be made.
 - The direction of improving the QM treatment is summarized pictorially in Jabob's ladder:
- There are schemes which go beyond DFT:
 - GW method (for excitations or band gaps)
 - The Bethe Salpeter equation (BSE) for excitons (core hole electron)
 - Dynamical mean field theory (DMFT) based on DFT (wien2wannier)

Bloch-Theorem:

$$\left[-\frac{1}{2}\nabla^2 + V(r) \right] \Psi(r) = E\Psi(r)$$

1-dimensioanl case:

V(x) has lattice periodicity ("translational invariance"): V(x)=V(x+a)

The electron density $\rho(x)$ has also lattice periodicity, however, the wave function does **NOT**:

$$\rho(x) = \rho(x+a) = \Psi^*(x)\Psi(x) \qquad but:$$

$$\Psi(x+a) = \mu\Psi(x) \implies \mu^*\mu = 1$$

Application of the translation τ g-times:

$$\tau^g \Psi(x) = \Psi(x + ga) = \mu^g \Psi(x)$$

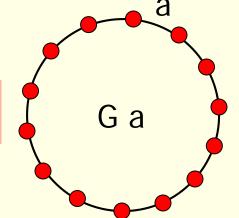

periodic boundary conditions:

The wave function must be uniquely defined: after G translations it must be identical (G a: periodicity volume):

$$\tau^{G}\Psi(x) = \Psi(x + Ga) = \mu^{G}\Psi(x) = \Psi(x)$$

$$\Rightarrow \mu^{G} = 1$$

$$\mu = e^{2\pi i \frac{g}{G}}$$
 $g = 0, \pm 1 \pm 2,$

$$\mu = e^{2\pi i \frac{g}{G}}$$

$$g = 0, \pm 1 \pm 2, \dots$$

$$Def : \qquad k = \frac{2\pi}{a} \frac{g}{G}$$

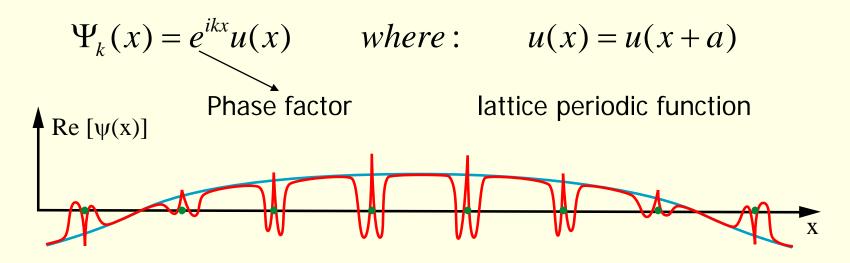

$$\mu = e^{ika}$$

Bloch condition:
$$\Psi(x+a) = e^{ika} \Psi(x) = \Psi_k$$

Bloch functions:

Wave functions with Bloch form:

Replacing k by k+K, where K is a reciprocal lattice vector, fulfills again the Bloch-condition.

 \rightarrow k can be restricted to the first Brillouin zone.

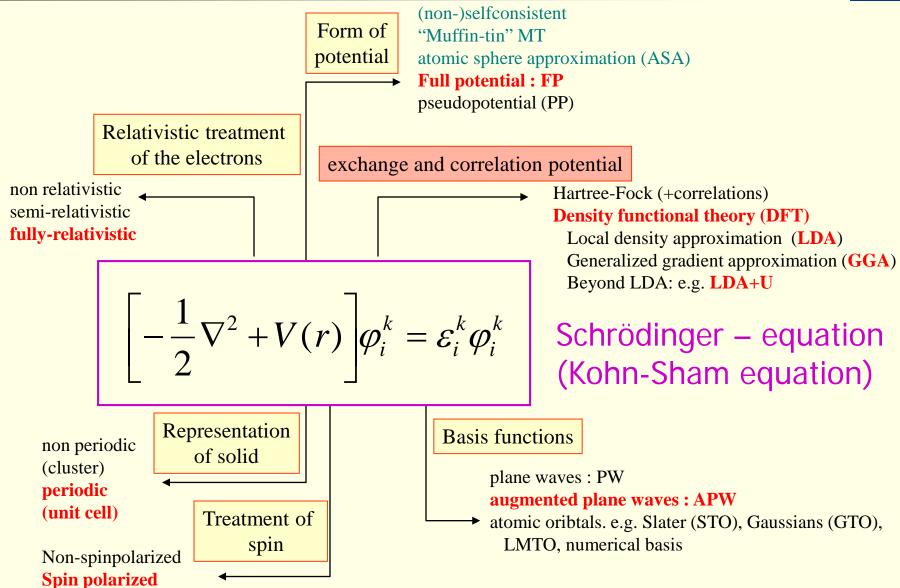

$$e^{i\frac{2\pi}{a}K} = 1 \qquad -\frac{\pi}{a} < k < \frac{\pi}{a}$$

(with certain magnetic order)

Concepts when solving Schrödingers-equation in solids

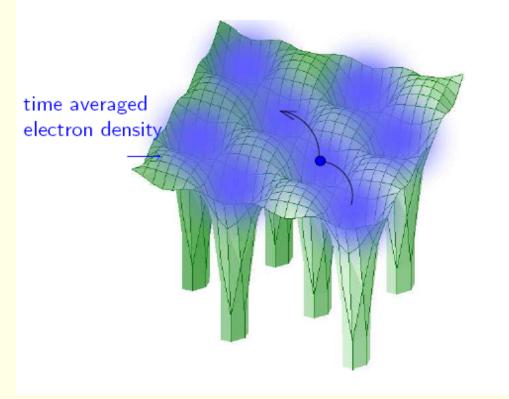

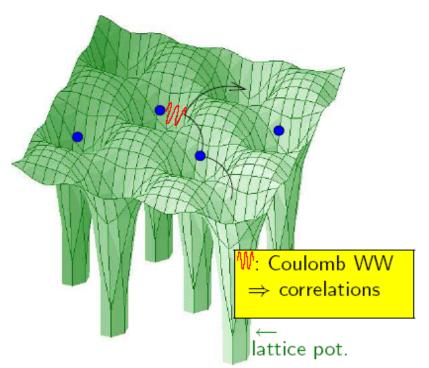

DFT vs. MBT (many body theory)

Two communities in solid state theory

	LDA bandstructure	many body theory
+	 material-specific, "ab initio" 	 electronic correlations
	 often successful, quantitative 	 qualitative understanding
_	 effective one-particle approach 	 model Hamiltonian

Ab-initio Hamiltonian

(non-relativistic/Born-Oppenheimer approximation)

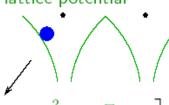

kinetic energy

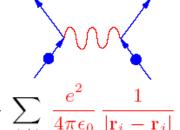

$$\frac{\hbar^2 \Delta_i}{2m} + \frac{1}{2m}$$

lattice potential

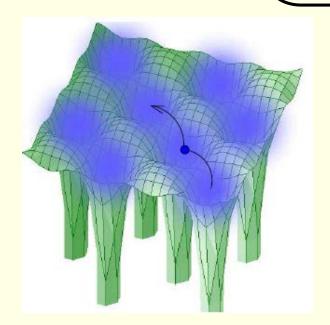

$$H = \sum_{i} \left[-\frac{\hbar^{2} \Delta_{i}}{2m_{e}} + \sum_{l} \frac{-e^{2}}{4\pi\epsilon_{0}} \frac{Z_{l}}{|\mathbf{r}_{i} - \mathbf{R}_{l}|} \right] + \frac{1}{2} \sum_{i \neq j} \frac{e^{2}}{4\pi\epsilon_{0}} \frac{1}{|\mathbf{r}_{i} - \mathbf{r}_{j}|}$$

Coulomb interaction

LDA bandstructure corresponds to

$$H_{\text{LDA}} = \sum_{i} \left[-\frac{\hbar^{2} \Delta_{i}}{2m_{e}} + \sum_{l} \frac{-e^{2}}{4\pi\epsilon_{0}} \frac{1}{|\mathbf{r}_{i} - \mathbf{R}_{l}|} + \int d^{3}r \frac{e^{2}}{4\pi\epsilon_{0}} \frac{1}{|\mathbf{r}_{i} - \mathbf{r}|} \rho(\mathbf{r}) + V_{xc}^{\text{LDA}}(\rho(\mathbf{r}_{i})) \right]$$

Coulomb potential:

- nuclei
- all electrons
- including self-interaction

Quantum mechanics:

- exchange
- correlation
- (partly) cancel self-interaction

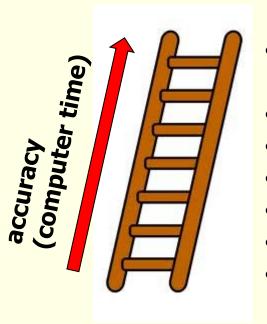

Jacob's ladder: The grand challenge:

- Find a functional which leads to "DFT heaven":

- predictive power with chemical accuracy
- J. Perdew's "Jacob's ladder" into DFT heaven:

- DFT heaven
- unoccupied orbitals (ACFDT-RPA)
- occupied orbitals (hybrid-DFT)
- meta-GGAs (kinetic energy density τ)
- GGA $(\nabla \rho)$
- LDA (ρ)
- Hartree

DFT Density Functional Theory

<u>Hohenberg-Kohn theorem</u>: (exact)

The total energy of an interacting inhomogeneous electron gas in the presence of an external potential $V_{ext}(r)$ is a functional of the density ρ

$$E = \int V_{ext}(\vec{r})\rho(\vec{r})d\vec{r} + F[\rho]$$

Kohn-Sham: (still exact!)

$$E = T_o[\rho] + \int V_{ext} \rho(\vec{r}) d\vec{r} + \frac{1}{2} \int \frac{\rho(\vec{r}) \rho(\vec{r}')}{|\vec{r}' - \vec{r}|} d\vec{r} d\vec{r}' + E_{xc}[\rho]$$

E_{kinetic} non interacting

E_{ne}

 $E_{coulomb}$ E_{ee} E_{xc} exchange-correlation

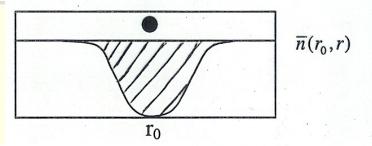

In KS the many body problem of interacting electrons and nuclei is mapped to a one-electron reference system that leads to the same density as the real system.

Exchange and correlation

 $\overline{n}(r_0, r) = \underline{n}(r) + h(r_0, r)$

• We divide the density of the N-1 electron system into the total density n(r) and an exchangecorrelation hole:

Properties of the exchange-correlation hole:

- Locality
- Pauli principle
- the hole contains ONE electron
- The hole must ne negative

$$h(r_0, r) \xrightarrow{|r-r_0| \to \infty} 0$$

$$h(r_0, r) \xrightarrow{|r-r_0| \to 0} -n(r_0)$$

$$\int dr \ h(r_0, r) = -1$$

$$h(r_0, r) \le 0$$

- The exchange hole affects electrons with the same spin and accounts for the Pauli principle
- In contrast, the correlation-hole accounts for the Coulomb repulsion of electrons with the opposite spin. It is short range and leads to a small redistribution of charge. The correlation hole contains NO charge:

$$\int dr \ h_c(r_0, r) = 0$$

Kohn-Sham equations

LDA, GGA

$$E = T_o[\rho] + \int V_{ext} \rho(\vec{r}) d\vec{r} + \frac{1}{2} \int \frac{\rho(\vec{r})\rho(\vec{r}')}{|\vec{r}' - \vec{r}|} d\vec{r} d\vec{r}' + E_{xc}[\rho]$$

1-electron equations (Kohn Sham)

vary ρ

$$\{-\frac{1}{2}\nabla^{2} + V_{ext}(\vec{r}) + V_{C}(\rho(\vec{r})) + V_{xc}(\rho(\vec{r}))\}\Phi_{i}(\vec{r}) = \varepsilon_{i}\Phi_{i}(\vec{r})$$

$$\int \frac{\rho(\vec{r})}{|\vec{r}' - \vec{r}|} d\vec{r}$$

$$\frac{\partial E_{xc}(
ho)}{\partial
ho}$$

$$\frac{-\mathsf{Z/r}}{\int \frac{\rho(\vec{r})}{|\vec{r}' - \vec{r}|} d\vec{r}} \qquad \frac{\partial E_{xc}(\rho)}{\partial \rho} \qquad \qquad \rho(\vec{r}) = \sum_{\varepsilon_i \leq E_F} |\Phi_i|^2$$

$$E_{xc}^{LDA} \propto \int \rho(r) \ \varepsilon_{xc}^{ ext{hom.}}[
ho(r)] \ dr$$
 $E_{xc}^{GGA} \propto \int \rho(r) \ F[
ho(r), \nabla \rho(r)] \ dr$
treats both, exchange and correlation effects, but approximately

New (better ?) functionals are still an active field of research

ESSENCE OF DENSITY-FUNTIONAL THEORY

- Every observable quantity of a quantum system can be calculated from the density of the system ALONE (Hohenberg, Kohn, 1964).
- The density of particles interacting with each other can be calculated as the density of an auxiliary system of non-interacting particles (Kohn, Sham, 1965).

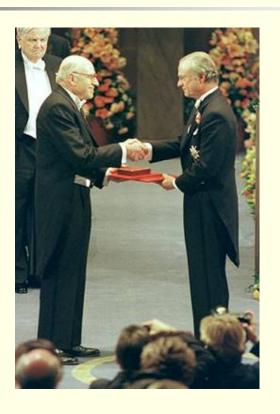

Walter Kohn, Nobel Prize 1998 Chemistry

"Self-consistent Equations including Exchange and Correlation Effects"

W. Kohn and L. J. Sham, Phys. Rev. 140, A1133 (1965)

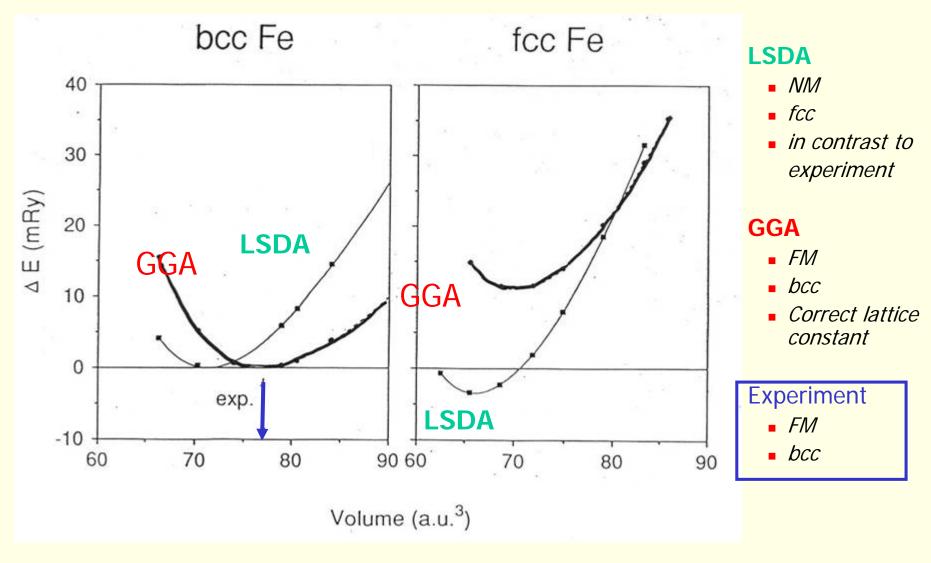

50 years ago

Literal quote from Kohn and Sham's paper:"... We do not expect an accurate description of chemical binding."

DFT ground state of iron

DFT thanks to Claudia Ambrosch (previously in Graz)

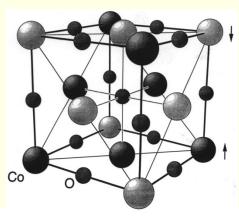

GGA follows LDA

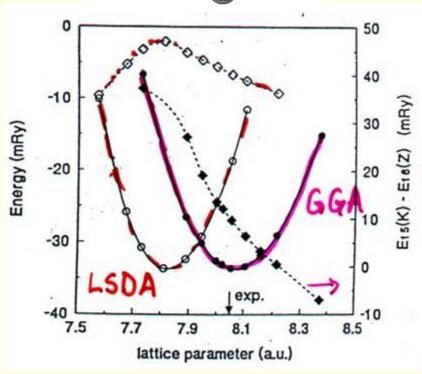

CoO AFM-II total energy, DOS

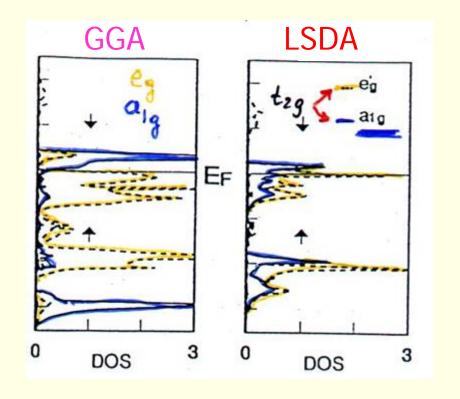

CoO

- in NaCl structure
- antiferromagnetic: AF II
- insulator
- t_{2g} splits into a_{1g} and e_{g}

AM05	0.005	0.035	0.01	0.77
PBE	0.051	0.055	1.05	1.18

Can LDA be improved?

- better GGAs and meta-GGAs $(\rho, \nabla \rho, \tau)$:
 - usually improvement, but often too small.
- LDA+U: for correlated 3d/4f electrons, treat strong Coulomb repulsion via Hubbard U parameter (cheap, "empirical U"?)
- Exact exchange: imbalance between exact X and approximate C
 - hybrid-DFT (mixing of HF + GGA; "mixing factor" ?)
 - exact exchange + RPA correlation (extremely expensive)
- GW: gaps in semiconductors, expensive!
- Quantum Monte-Carlo: very expensive
- DMFT: for strongly correlated (metallic) d (f) -systems (expensive)

Treatment of exchange and correlation

Approximations for E_{xc}

- ► LDA: $E_{xc}^{LDA} = \int f(\rho(\mathbf{r}))d^3r$
- ► GGA: $E_{xc}^{GGA} = \int f(\rho(\mathbf{r}), |\nabla \rho(\mathbf{r})|) d^3r$

- ► MGGA: $E_{xc}^{MGGA} = \int f(\rho(\mathbf{r}), |\nabla \rho(\mathbf{r})|, \nabla^2 \rho(\mathbf{r}), t(\mathbf{r})) d^3r$
- ► LDA+*U*: $E_{xc}^{LDA+U} = E_{xc}^{LDA} + E_{ee} E_{dc}$
- ► GGA+U: $E_{xc}^{GGA+U} = E_{xc}^{GGA} + E_{ee} E_{dc}$
- hybrid: $E_{xc}^{hybrid} = E_{xc}^{DFT} + \alpha \left(E_{x}^{HF} E_{x}^{DFT} \right)$ where

$$E_{x}^{HF} = -\frac{1}{2} \sum_{\sigma} \sum_{\substack{n,\mathbf{k} \\ l \neq l}} w_{\mathbf{k}} w_{\mathbf{k}'} \int \int \frac{\psi_{n\mathbf{k}}^{\sigma*}(\mathbf{r}) \psi_{n'\mathbf{k}'}^{\sigma*}(\mathbf{r}') \psi_{n'\mathbf{k}'}^{\sigma}(\mathbf{r}) \psi_{n\mathbf{k}}^{\sigma}(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} d^{3}r d^{3}r'$$

Hybrid functional: only for (correlated) electrons

 Only for certain atoms and electrons of a given angular momentum

$$E_{\mathrm{xc}}^{\mathrm{hybrid}} = E_{\mathrm{xc}}^{\mathrm{DFT}}[\rho^{\sigma}] + \alpha \left(E_{\mathrm{x}}^{\mathrm{HF}}[n_{m_{i}m_{j}}^{\sigma}] - E_{\mathrm{x}}^{\mathrm{DFT}}[\rho_{\ell}^{\sigma}] \right)$$

$$E_{\rm x}^{\rm HF}[n_{m_im_j}^{\sigma}] = -rac{1}{2}\sum_{\sigma}\sum_{m_1,m_2,m_3,m_4}^{\ell}n_{m_1m_2}^{\sigma}n_{m_3m_4}^{\sigma}\langle m_1m_3|v_{\rm ee}|m_4m_2
angle$$

$$\langle m_1 m_2 | v_{\text{ee}} | m_3 m_4 \rangle = \sum_{k=0}^{2\ell} a_k F_k$$

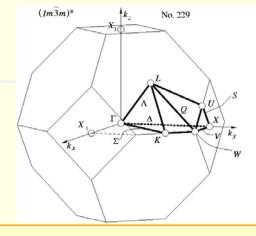

The Slater integrals F_k are calculated according to P.Novák et al., phys.stat.sol (b) **245**, 563 (2006)

S

Structure: $a,b,c,\alpha,\beta,\gamma,R_{\alpha}$, ...

unit cell atomic positions

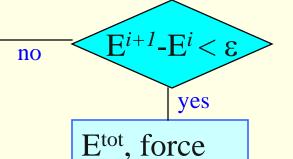

Structure optimization

iteration *i*

DFT Kohn-Sham

 $V(\rho) = V_C + V_{xc}$ Poisson, DFT

Minimize E, force $\rightarrow 0$

properties

k ∈ **IBZ** (irred.Brillouin zone)

Kohn Sham

$$[-\nabla^2 + V(\rho)]\psi_k = E_k \psi_k$$

$$\psi_k = \sum_{k_n} C_{k_n} \Phi_{k_n}$$

k

Variational method

$$\frac{\delta < E >}{\delta C_{k_n}} = 0$$

Generalized eigenvalue problem

$$HC = ESC$$

$$\rho = \sum_{E_k \le E_F} \psi_k^* \psi_k$$

Solving Schrödingers equation:

- Ψ cannot be found analytically
- complete "numerical" solution is possible but inefficient
- Ansatz:
 - linear combination of some "basis functions"

$$\Psi_k = \sum_{K_n} c_{k_n} \Phi_{k_n}$$

different methods use different basis sets!

• finding the "best" wave function using the variational principle:

$$\langle E_k \rangle = \frac{\langle \Psi_k^* | H | \Psi_k \rangle}{\langle \Psi_k^* | \Psi_k \rangle} \qquad \frac{\partial E_k}{\partial c_{k_n}} = 0$$

this leads to the famous "Secular equations", i.e. a set of linear equations which in matrix representation is called "generalized eigenvalue problem"

$$HC = ESC$$

H, S: hamilton and overlap matrix; C: eigenvectors, E: eigenvalues

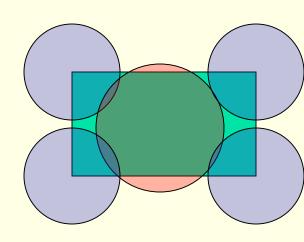

Basis Sets for Solids

- plane waves
 - pseudo potentials
 - PAW (projector augmented wave) by P.E.Blöchl
- space partitioning (augmentation) methods
 - LMTO (linear muffin tin orbitals)
 - ASA approx., linearized numerical radial function
 - + Hankel- and Bessel function expansions
 - full-potential LMTO
 - ASW (augmented spherical wave)
 - similar to LMTO
 - KKR (Korringa, Kohn, Rostocker method)
 - solution of multiple scattering problem, Greens function formalism
 - equivalent to APW
 - (L)APW (linearized augmented plane waves)

- LCAO methods
 - Gaussians, Slater, or numerical orbitals, often with PP option)

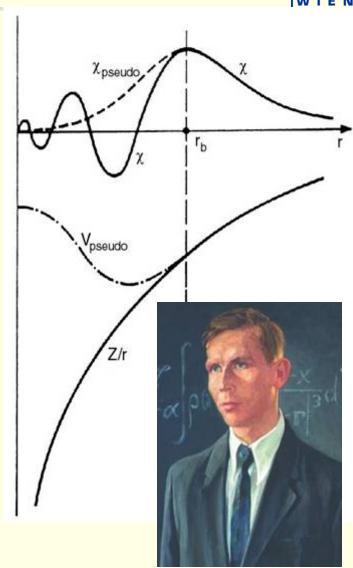

pseudopotential plane wave methods

- plane waves form a "complete" basis set, however, they "never" converge due to the rapid oscillations of the atomic wave functions χ close to the nuclei
- let 's get rid of all core electrons and these oscillations by replacing the strong ion-electron potential by a much weaker (and physically dubious) pseudopotential
- Hellmann´s 1935 combined approximation method

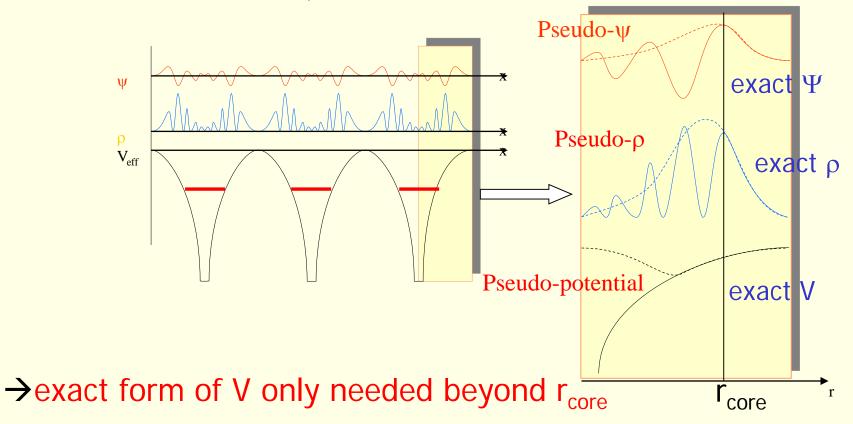

"real" potentials vs. pseudopotentials

- "real" potentials contain the Coulomb singularity -Z/r
- the wave function has a cusp and many wiggles,
- chemical bonding depends mainly on the overlap of the wave functions between neighboring atoms (in the region between the nuclei) ->

APW based schemes

- APW (J.C.Slater 1937)
 - Non-linear eigenvalue problem
 - Computationally very demanding
- LAPW (O.K.Anderssen 1975)
 - Generalized eigenvalue problem
 - Full-potential

K.Schwarz, P.Blaha, G.K.H.Madsen, Comp.Phys.Commun.**147**, 71-76 (2002)

K.Schwarz,

DFT calculations of solids with LAPW and WIEN2k Solid State Chem. **176**, 319-328 (2003)

- Local orbitals (D.J.Singh 1991)
 - treatment of semi-core states (avoids ghostbands)
- APW+lo (E.Sjöstedt, L.Nordstörm, D.J.Singh 2000)
 - Efficiency of APW + convenience of LAPW
 - Basis for

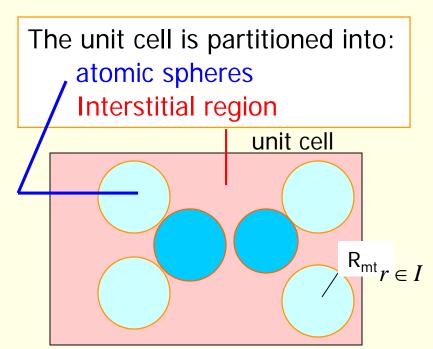

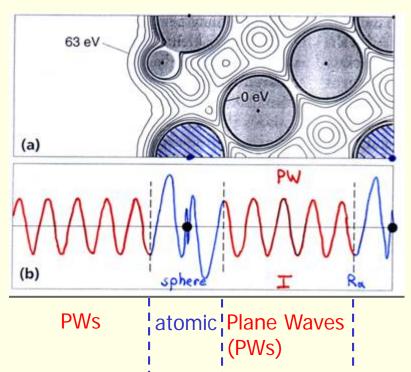

K.Schwarz, P.Blaha, S.B.Trickey, Molecular physics, **108**, 3147 (2010)

APW Augmented Plane Wave method

Basis set:

PW:
$$e^{i(\vec{k}+\vec{K}).\vec{r}}$$

Atomic partial waves

$$\sum_{\ell m} A_{\ell m}^K u_{\ell}(r',\varepsilon) Y_{\ell m}(\hat{r}')$$

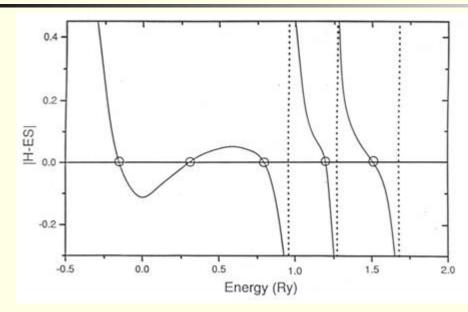

join

 $u_l(r,\varepsilon)$ are the numerical solutions of the radial Schrödinger equation in a given spherical potential for a particular energy ε $A_{lm}{}^{K}$ coefficients for matching the PW

Slater's APW (1937)

H Hamiltonian S overlap matrix

Atomic partial waves
$$\sum_{\ell m} a_{\ell m}^K u_{\ell}(r', \varepsilon) Y_{\ell m}(\hat{r}')$$

Energy dependent basis functions lead to a

Non-linear eigenvalue problem

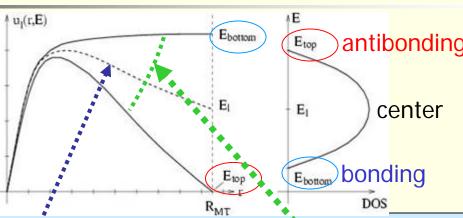

Numerical search for those energies, for which the det|H-ES| vanishes. Computationally very demanding. "Exact" solution for given MT potential!

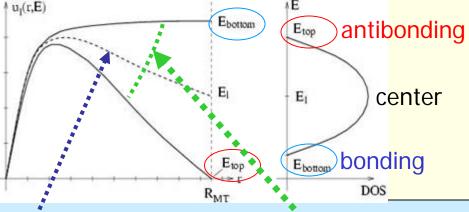

Linearization of energy dependence

LAPW suggested by

O.K.Andersen, Phys.Rev. B 12, 3060 (1975)

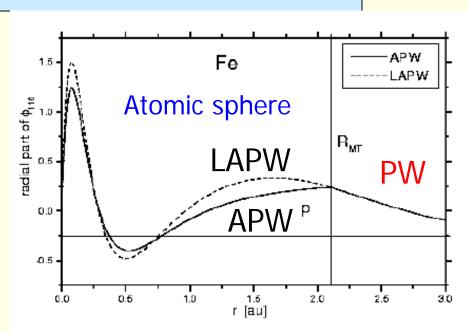

$$\Phi_{k_n} = \sum_{\ell m} [A_{\ell m}(k_n)\dot{u}_{\ell}(E_{\ell},r) + B_{\ell m}(k_n)\dot{u}_{\ell}(E_{\ell},r)]Y_{\ell m}(\hat{r})$$

expand u_i at fixed energy E_i and add $\dot{u}_1 = \partial u_1 / \partial \varepsilon$

 A_{lm}^{k} , B_{lm}^{k} : join PWs in value and slope

- → General eigenvalue problem (diagonalization)
- → additional constraint requires more PWs than APW

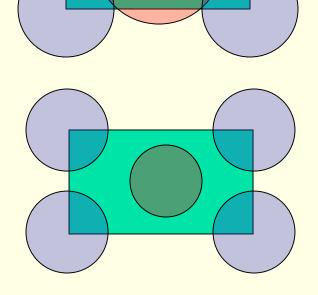

shape approximations to "real" potentials

- Atomic sphere approximation (ASA)
 - overlapping spheres "fill" all volume
 - potential spherically symmetric

- non-overlapping spheres with spherically symmetric potential +
- interstitial region with V=const.

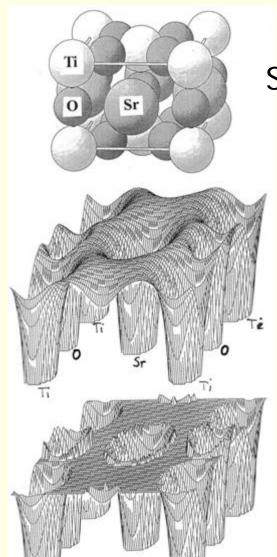

- "full"-potential
 - no shape approximations to V

Full-potential in LAPW (A.Freeman et al)

SrTiO₃

Full potential

Muffin tin approximation

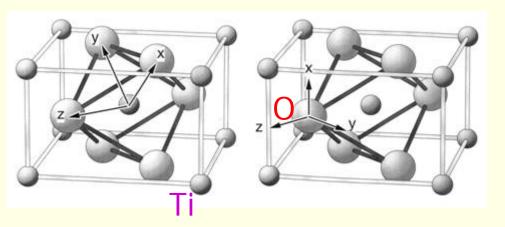

TiO₂ rutile

 The potential (and charge density) can be of general form (no shape approximation)

$$V(r) = \begin{cases} \sum_{LM}^{\sum_{LM} (r) Y_{LM}(\hat{r})} & r < R_{\alpha} \\ \sum_{K} V_{K} e^{i\vec{K}.\vec{r}} & r \in I \end{cases}$$

 Inside each atomic sphere a local coordinate system is used (defining LM)

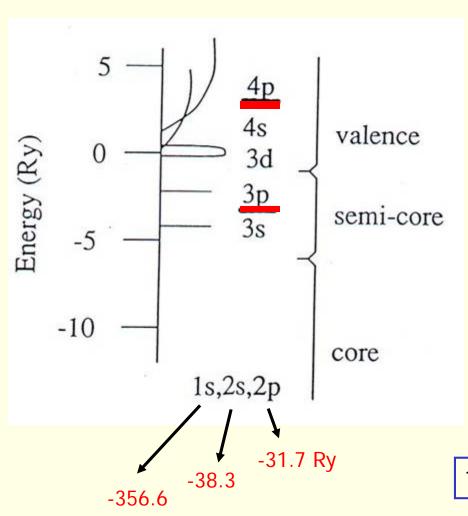

Core, semi-core and valence states

For example: Ti

Valences states

- High in energy
- Delocalized wavefunctions
- Semi-core states
 - Medium energy
 - Principal QN one less than valence (e.g. in Ti 3p and 4p)
 - not completely confined inside sphere (charge leakage)
- Core states
 - Low in energy
 - Reside inside sphere

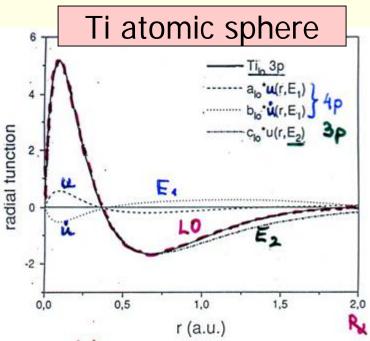

1 Ry = 13.605 eV

Local orbitals (LO)

$$\Phi_{LO} = [A_{\ell m} u_{\ell}^{E_1} + B_{\ell m} \dot{u}_{\ell}^{E_1} + C_{\ell m} u_{\ell}^{E_2}] Y_{\ell m}(\hat{r})$$

LOs

- are confined to an atomic sphere
- have zero value and slope at R
- Can treat two principal QN n for each azimuthal QN ℓ (e.g. 3p and 4p)
- Corresponding states are strictly orthogonal
 - (e.g.semi-core and valence)
- Tail of semi-core states can be represented by plane waves
- Only slightly increases the basis set (matrix size)

D.J.Singh, Phys.Rev. B 43 6388 (1991)

An alternative combination of schemes

E.Sjöstedt, L.Nordström, D.J.Singh, An alternative way of linearizing the augmented plane wave method, Solid State Commun. 114, 15 (2000)

- Use APW, but at fixed E_{I} (superior PW convergence)
- Linearize with additional local orbitals (lo) (add a few extra basis functions)

$$\Phi_{k_n} = \sum_{\ell m} A_{\ell m}(k_n) u_{\ell}(E_{\ell}, r) Y_{\ell m}(\hat{r})$$

$$\Phi_{lo} = [A_{\ell m} u_{\ell}^{E_1} + B_{\ell m} \dot{u}_{\ell}^{E_1}] Y_{\ell m}(\hat{r})$$

optimal solution: mixed basis

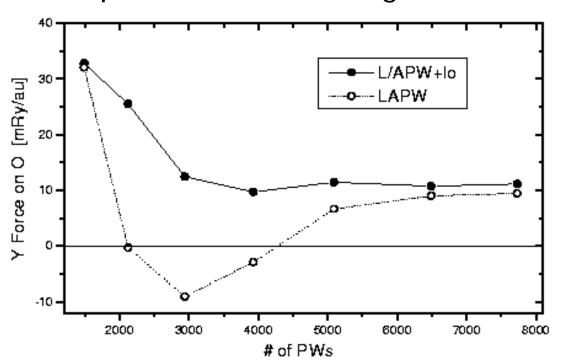

- use APW+lo for states, which are difficult to converge: (f or d- states, atoms with small spheres)
- use LAPW+LO for all other atoms and angular momenta

Improved convergence of APW+lo

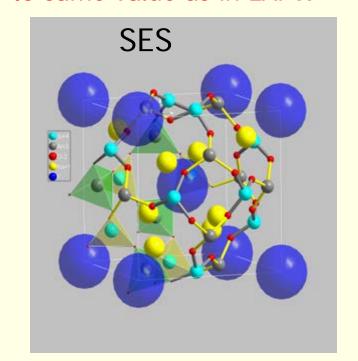

Representative Convergence:

SES (sodium electro solodalite)

K.Schwarz, P.Blaha, G.K.H.Madsen, Comp.Phys.Commun.**147**, 71-76 (2002)

- e.g. force (F_y) on oxygen in SES vs. # plane waves:
- in LAPW changes sign and converges slowly
- in APW+lo better convergence
- to same value as in LAPW

Summary: Linearization LAPW vs. APW

- Atomic partial waves
 - LAPW

$$\Phi_{k_n} = \sum_{\ell m} [A_{\ell m}(k_n) u_{\ell}(E_{\ell}, r) + B_{\ell m}(k_n) \dot{u}_{\ell}(E_{\ell}, r)] Y_{\ell m}(\hat{r})$$

APW+lo

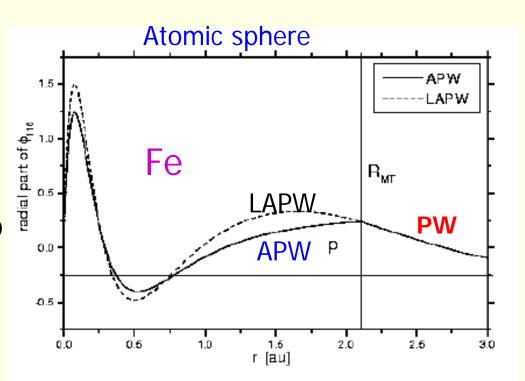

$$\Phi_{k_n} = \sum_{\ell m} A_{\ell m}(k_n) u_{\ell}(E_{\ell}, r) Y_{\ell m}(\hat{r})$$

Plane Waves (PWs)

$$e^{i(\vec{k}+\vec{K}_n).\vec{r}}$$

- match at sphere boundary
 - LAPW value and slope $A_{\ell m}(k_n), B_{\ell m}(k_n)$
 - APW value $A_{\ell m}(k_n)$

plus another type of local orbital (lo)

Method implemented in WIEN2k

E.Sjöststedt, L.Nordström, D.J.Singh, SSC 114, 15 (2000)

- Use APW, but at fixed E_{I} (superior PW convergence)
- Linearize with additional lo (add a few basis functions)

optimal solution: mixed basis

- use APW+lo for states which are difficult to converge: (f- or d- states, atoms with small spheres)
- use LAPW+LO for all other atoms and angular momenta

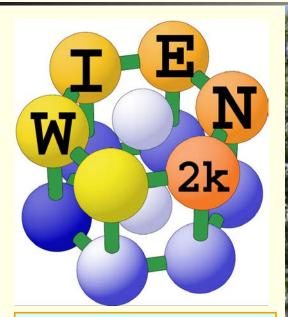

A summary is given in

K.Schwarz, P.Blaha, G.K.H.Madsen, Comp.Phys.Commun. 147, 71-76 (2002)

WIEN2k 入門

WIEN-code は 1980 年ごろから,グループの指導者である Karlheinz Schwarz によって書き始められ,1990 年に最初の copyrighted version の WIEN が発表された.その後 UNIX versionとなり,WIEN93,WIEN95,WIEN97 を経て,Fortran90 対応の WIEN2k へと改良・拡張されてきた *1 .基礎となるシュレーディンガー方程式はコーン・シャム方程式であり,バンド計算法は主として FLAPW 法,ポテンシャルは LSDA,GGA などである.最新の WIEN2k では,APW+lo も取り入れられており,ポテンシャルとしては電子相関が強いときに必要であると云われている補正 +U も扱えるようになっている.また,並列計算機を使えば,極めて複雑な結晶も計算の対象とすることができる.

(L)APW methods

APW + local orbital method (linearized) augmented plane wave method

Total wave function

$$\Psi_k = \sum_{K_n} C_{k_n} \phi_{k_n}$$

 $\Psi_k = \sum C_{k_n} \phi_{k_n}$ n...50-100 PWs /atom

Variational method:

$$=\frac{<\Psi/H/\Psi>}{<\Psi/\Psi>}$$
 $\frac{\delta< E>}{\delta C_{k_n}}=0$

upper bound

minimum

HC=ESCGeneralized eigenvalue problem:

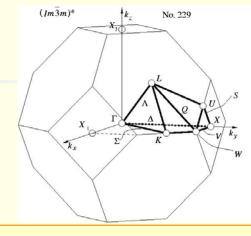

Diagonalization of (real or complex) matrices of size 10.000 to 50.000 (up to 50 Gb memory)

S

Structure: $a,b,c,\alpha,\beta,\gamma,R_{\alpha}$, ...

unit cell atomic positions

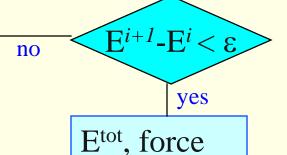

Structure optimization

iteration i

DFT Kohn-Sham

 $V(\rho) = V_C + V_{xc}$ Poisson, DFT

Minimize E, force $\rightarrow 0$

properties

k ∈ **IBZ** (irred.Brillouin zone)

Kohn Sham

$$[-\nabla^2 + V(\rho)]\psi_k = E_k \psi_k$$

 $\psi_k = \sum_{k_n} C_{k_n} \Phi_{k_n}$

k

Variational method

$$\frac{\delta < E >}{\delta C_{k_n}} = 0$$

Generalized eigenvalue problem

$$HC = ESC$$

$$\rho = \sum_{E_k \le E_F} \psi_k^* \psi_k$$

The Brillouin zone (BZ)

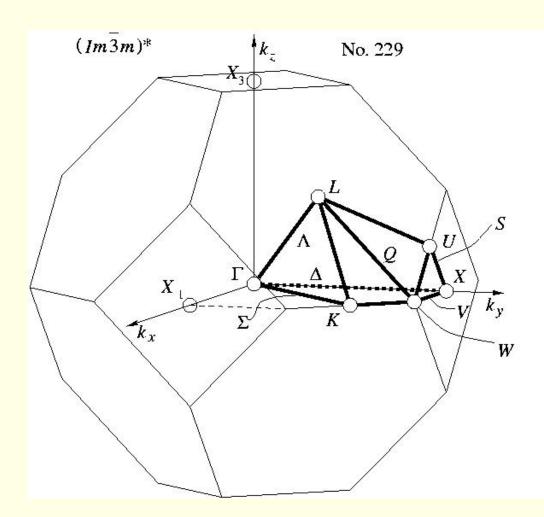

Irreducible BZ (IBZ)

- The irreducible wedge
- Region, from which the whole BZ can be obtained by applying all symmetry operations

Bilbao Crystallographic Server:

- www.cryst.ehu.es/cryst/
- The IBZ of all space groups can be obtained from this server
- using the option KVEC and specifying the space group (e.g. No.225 for the fcc structure leading to bcc in reciprocal space, No.229)

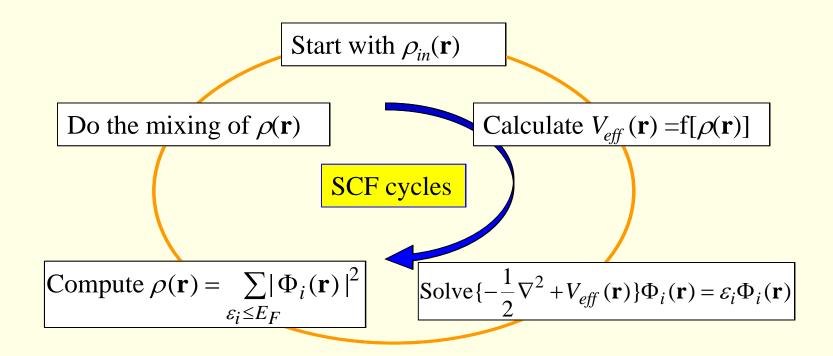

Self-consistent field (SCF) calculations

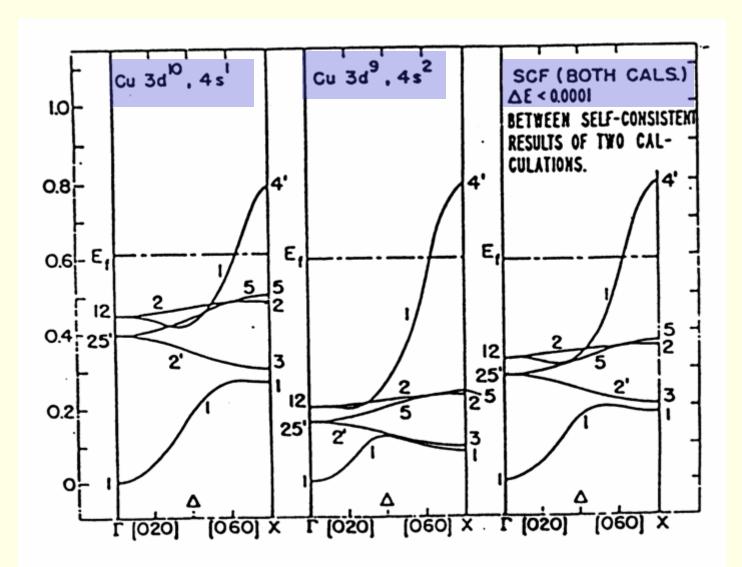

- In order to solve HΨ=EΨ we need to know the potential V(r)
- for V(r) we need the electron density $\rho(r)$
- the density $\rho(r)$ can be obtained from $\Psi(r)^*\Psi(r)$
- ?? $\Psi(r)$ is unknown before $H\Psi = E\Psi$ is solved ??

Band structure of fcc Cu

Program structure of WIEN2k

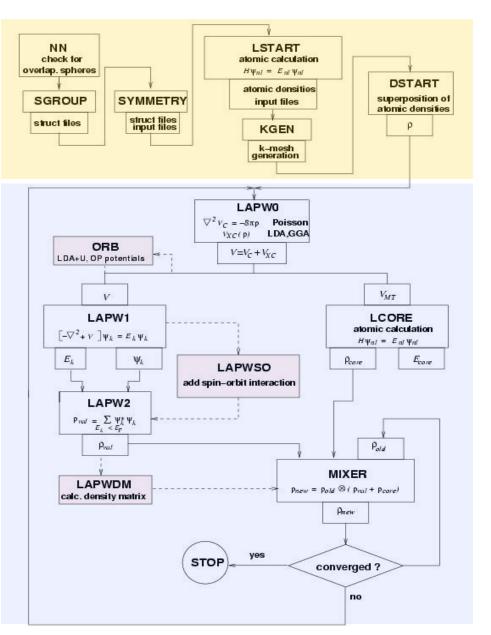

init_lapw

- initialization
- symmetry detection (F, I, Ccentering, inversion)
- input generation with recommended defaults
- quality (and computing time) depends on k-mesh and R.Kmax (determines #PW)

run_lapw

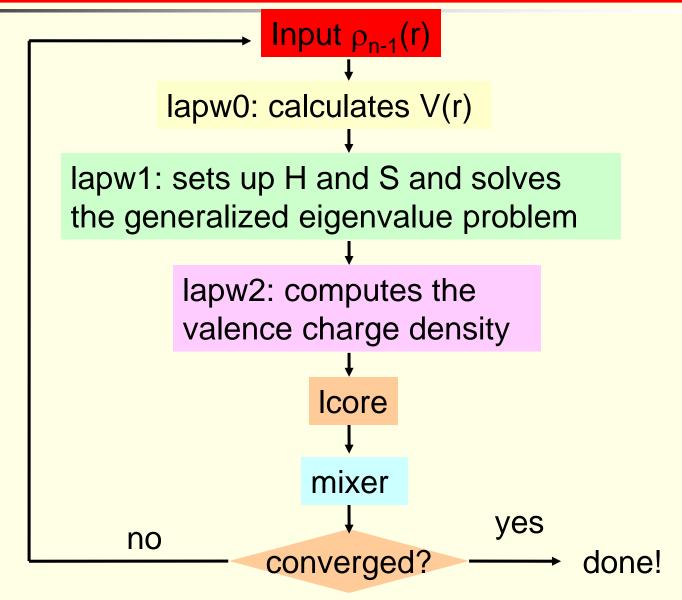

- scf-cycle
- optional with SO and/or LDA+U
- different convergence criteria (energy, charge, forces)
- save_lapw tic_gga_100k_rk7_vol0
 - cp case.struct and clmsum files,
 - mv case.scf file
 - rm case.broyd* files

Flow Chart of WIEN2k (SCF)

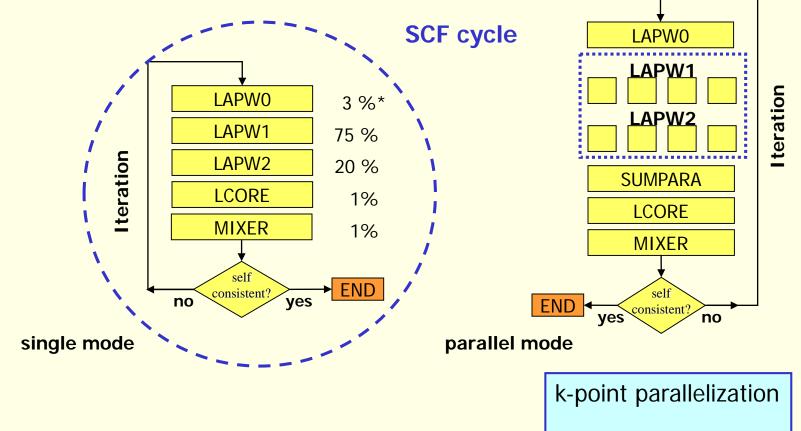

WIEN2k: P. Blaha, K. Schwarz, G. Madsen, D. Kvasnicka, and J. Luitz

Workflow of a WIEN2k calculation

- individual FORTRAN programs linked by shell-scripts
- the output of one program is input for the next
- lapw1/2 can run in parallel on many processors

^{*} fraction of total computation time

Advantage/disadvantage of WIEN2k

- + robust all-electron full-potential method (new effective mixer)
- + unbiased basisset, one convergence parameter (LDA-limit)
- + all elements of periodic table (comparable in CPU time), metals
- + LDA, GGA, meta-GGA, LDA+U, spin-orbit
- + many properties and tools (supercells, symmetry)
- + w2web (for novice users)
- ? speed + memory requirements
 - + very efficient basis for large spheres (2 bohr) (Fe: 12Ry, O: 9Ry)
 - less efficient for small spheres (1 bohr) (O: 25 Ry)
 - large cells, many atoms (n³, but new iterative diagonalization)
 - full H, S matrix stored → large memory required
 - + effective dual parallelization (k-points, mpi-fine-grain)
 - + many k-points do not require more memory
- no stress tensor
- no linear response

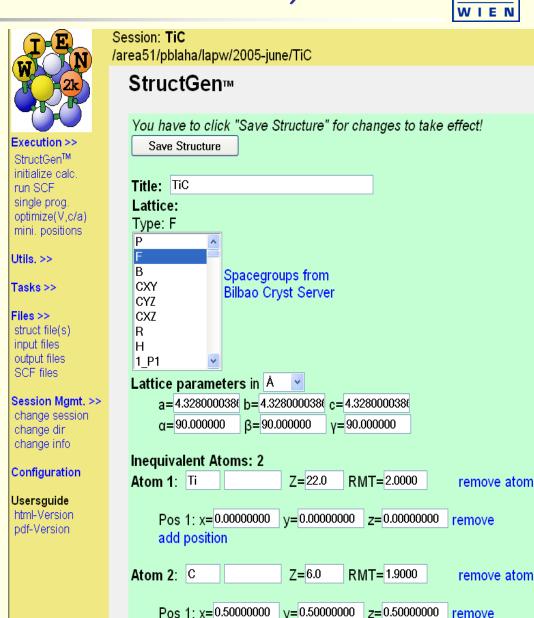

w2web GUI (graphical user interface)

remove

- Structure generator
 - spacegroup selection
 - import cif file
- step by step initialization
 - symmetry detection
 - automatic input generation
- SCF calculations
 - Magnetism (spin-polarization)
 - Spin-orbit coupling
 - Forces (automatic geometry optimization)
- **Guided Tasks**
 - Energy band structure
 - DOS
 - Electron density
 - X-ray spectra
 - **Optics**

Crucial aspects for a simulation

Theory vs. experiment: Agreement or disagreement: What can cause it?

Structure model:

unit cell supercell surface Quantum mechanics:

mean field (DFT)
many body theory
ground vs. excited states

Convergence:

basis sets **k**-points Other effects:

temperature T>0 K pressure

stoichiometry disorder impurities, defects electron core-hole satellites all electron

vacuum supercell l quantum n. average vibrations

These aspects need to be considered when comparing theory with experiment.

Vienna, city of music and the Wien2k code
